ABSTRACT

A conveyor roller has a drum shell and an end lid that has an end lid, an embossed spring band, and a mounting face that is affixed to an axial end of the drum shell. The end lid has a cylindrical geometry that mates with the mounting face, whereby the embossed spring band is compressed by an interference fit between the two mating cylindrical geometries. A polymeric seal is disposed between the inward face of the end lid and the outward face of the drum shell, near the outer circumference of the end lid. Thus, the end lid maintains a spring force against the polymeric seal. The end lid has a ring compression geometry for exerting a compressive force on the polymeric seal as the end lid is retained against the drum shell by the embossed spring band. A cleaning system has a shaft with cleaning conduits, inlet and outlet ports, and an end lid.

CONVEYOR ROLLER ARRANGEMENT

RELATIONSHIP TO OTHER APPLICATION(S)

This application claims the benefit of the filing dates of: U.S. Provisional Patent Application Ser. No. 61/522,587, filed Aug. 11, 2011; U.S. Provisional Patent Application Ser. No. 61/590,790, filed Jan. 25, 2012; and U.S. Provisional Patent Application Ser. No. 61/665,888, filed Jun. 28, 2012, the disclosures of all of which are incorporated herein by reference.

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates generally to high powered compact electric motors, and more particularly, to a motor and reducer system, the motor being an outer rotor motor that is particularly adaptable for motorized drums used in a conveyor or the like to drive a conveyor belt or the like around the drum shell, and more particularly to sanitary conveyor motorized drum applications. In addition, this invention relates to a sanitation system that monitors fluid pressures within high powered compact electric motors, as well as fluid pressures within conveyor rollers and supporting structures, the sanitation system being particularly adaptable to sanitary conveyor applications.

2. Description of the Related Art

Motorized drums are predominantly configured so that a motor and reducer are disposed within a drum shell and the rotations of the motor are reduced by the reducer and then transmitted to the drum shell so that when the external shafts are secured to the frame of a conveyor, the drum shell is able to rotate. In some embodiments, the drum shell drives a flat belt, or toothed belt, or modular belt.

The motorized drum that is currently available has a drum shell and the motor and reducer are housed within this drum shell. Bearings and seals are disposed at both end sections of the drum shell with end covers for closing these end sections disposed between the bearings and the drum shell. Labyrinths are frequently used in the end covers to protect the seals from high pressure water that is used to clean food processing plants. There are employed first and second mounting shafts that enable rotation relative to the drum shell. Accordingly, the drum shell rotates about a central axis of the first and second mounting shafts. The first mounting shaft contains a hollow portion through which the motor wiring leads, which are connected to the motor, exit the motorized drum. The known motorized drum is partially filled with oil, which lubricates the open gear box and bearings, and transmits the heat from the motor to the inner periphery of the roller drum as the oil moves throughout the motorized drum.

The known motor has an internal rotor with a shaft attached. This motor rotor shaft also functions as the input shaft for the reducer. The reducer has an output shaft that is coupled to the shell while the fixed reference point of the reducer (it's housing) rotates relative to the drum shell and has no rotary motion relative to the motor stator and mounting shafts. When the motor is energized, the shaft of the known motor rotates. The speed of this rotation is reduced by the reducer, and the reducer output power is then transmitted to the drum shell via the output shaft, thereby driving the drum shell into rotation. In order to achieve smooth operation, the central axis of the motor output shaft and the central axis of the first and second mounting shafts must be in substantial alignment with each other.

The food processing industry is often a twenty four hour cycle that typically employs two shifts of production and one shift of cleaning. The focus is on high throughput, and downtime is not acceptable. Equipment failure must be repairable immediately or replaceable with spare parts.

Existing motorized drums are essentially custom products. Four variables are involved in the selection of a motorized drum. These are: belt speed, belt width, belt pull, and pulley diameter. Additional options may also be included in the analysis, such as lagging, various electrical options, and the need for reinforced shafts.

Currently, the industry predominantly uses AC induction motors that operate at a fixed speed. A motor speed and a gear reduction arrangement must be selected to provide the highest possible belt pull for the application, while creating the lowest amount of heat. The heat issue is critical as the motorized drum is a closed system that renders removal of heat to be very difficult. Therefore a large number of motors, in different poles, must be considered for each diameter along with multiple two and three stage gear boxes.

Currently, the industry uses helical gearing that is limited by the diameter and axial length of the pulley. Therefore, to transmit the necessary torque through the gear box, it is often necessary to use a larger diameter pulley, which is usually not preferred by the market.

In order to have the correct motorized drum available for each application, the manufacturer would need to stock thousands of possibilities, which is not financially feasible. Therefore, each motor is custom built based upon the four variables noted above, resulting in unacceptably long lead times to the industry. As zero downtime is a market requirement, the food processor customer must stock spares of all the motors he uses. This can be as many as several hundreds of motors, requiring high capital investment and cost.

Therefore, it is an object of this invention to create a modular motorized drum that can eliminate the customer's need for a large spare parts inventory by means of a motorized drum produced in its minimal axial length (hereafter, base unit), that includes a mounting face system on one end of the motorized drum onto which various components can be mounted. Such components include end lids, additional extension drum shells and an extension shaft that can accommodate the attachment of sprockets, among others.

It is a further object of this invention to increase the torque density of the motorized drum so that the modular base unit can be a single unit in a preferred diameter and axial length.

It is another object of this invention to provide a motor that maintains a relatively constant torque and efficiency curve across a broad speed range so that a single base unit can be used in all applications within a given production plant.

Customers require spares and spare parts because of the high likelihood of catastrophic failure present in the current art. One contributor to catastrophic failure among current art is the high belt pull and/or tension of the belt on the motorized drum that causes severe and immediate damage to the internal components. Existing motorized drums use segmented or partial shafts. A partial shaft is fixed to the conveyor and enters the motorized drum and is attached to a motor flange. The motor flange is attached to the motor, and the motor is attached to a gear box. The gear box is attached to a partial shaft that exits the motorized drum and is then affixed to the conveyor. These partial shaft segments are either substantially coaxial or are parallel with the motor shaft portion. The dividing of the shaft axially, however, diminishes the transaxial rigidity of the shaft, causing flexure and misalignment between the partial shafts and thus between the motor and transmission.

Such misalignment creates inefficiency, high wear, and often catastrophic failure of the transmission or motor. Prior art efforts to alleviate this problem by include increasing the diameter of the first or second mounting shaft within the motorized drum as the axial length of the motorized drum increases. Others in the art have sought to compensate by using axially longer end lids.

Therefore, it is an object of this invention to accommodate the misalignment between all components of the motorized drum and to accommodate, rather than minimize, the inherent forces causing deflection that enters the motorized drum.

Another significant problem with existing art is its inability to comply fully with the food safety demands of the market. First, it is noted that existing products are filled with oil in order to lubricate gears, bearings, and seals. The oil also transmits heat from the motor core to the shell, where it can be removed by conduction to the belt. Further, system inefficiencies create heat and build pressure in the system, forcing the oil to leak through the rubber lip seals—especially where scoring has occurred in the shaft at the seal. Oil leakage creates the risk of contamination of the food products.

Therefore, it is yet another object of this invention to eliminate the use of oil in the motorized drum.

Second, it is a significant problem with existing motor designs that harborage points exist in the exterior of the drum unit wherein bacterial colonies (i.e., pathogens) can grow. Examples of efforts to alleviate this problem include the use of a labyrinth in the end lid that is used to protect rotary shaft seals from high pressure washing. Also, external bolts and washers are used to connect the end lids to the drum shell, and further bacterial harborage regions are present between the drum shell and its end lids.

Therefore, it is a further object of the invention to eliminate harborage points where colonies of bacteria can flourish.

Third, existing motorized drums that drive modular conveyor belting or toothed driven belting, predominantly engage the belting by means of grooved rubber or polyurethane lagging. This lagging will crack, lift, or pit, thereby not only creating additional harborage points for bacteria, but also serving to isolate heat within the motor. The result is that currently available motors must be derated typically by approximately 18%. This means that more heat is created in relationship to the work performed because the motor is now running at decreased efficiency. The lagging therefore causes the pulley to take a longer period of time to reach steady state, and when it does reach the steady state condition, it does so at a higher temperature than would have been the case without the polymeric lagging, ultimately resulting in higher belt temperature. This additional heat must then be removed from the lagging by the conveyor belt. As the conveyor belt moves along the conveyor, the heat typically is removed from the belt either by convection into the environment or through conduction into the food product being conveyed. It is desired by food industry personnel that no heat from the drive system enter into the food product.

Other prior art arrangements drive modular conveyor belting or toothed driven belting by mounting sprockets to the drum shell instead of lagging. In such arrangements, the conveyor belt does not contact the drum shell directly, and therefore the drum motor still needs to be derated. Further, the sprockets, in their various mounting structures to the shell, create harborage points or dead spaces where bacterial colonies can grow.

Therefore, it is an object of this invention to reduce the steady state temperature of the motorized drum.

It is a further object of the invention to increase the rate of heat dissipation from the windings within the electrical motor to the inner surface of the drum shell.

Fourth, the food industry is concerned about potential cross contamination between the materials within a motorized drum and the food products being conveyed. Thus, the industry continues to seek a solution that will announce the presence of conditions that produce a likelihood of cross contamination. For example, many food industry customers require that red or blue dyes be added to a food grade oil so that when oil leaks, it can be detected. This proposed solution is not reliably effective because after the motorized drum is operated for a period of time, the oil becomes black and the red or blue dye no longer functions as an alert. Additionally, even when there is no actual leakage of oil, cross contamination is still a threat because bacterial colonies will grow in a labyrinth or seal unnoticed, which can then be propelled onto the conveyor during performance of a high pressure cleaning procedure.

Therefore, it is still another object of this invention not only to eliminate the use of oil in a closed system, but also to monitor the corruption of the rotary shaft seals and the static end lid seals in order to alert the system operator in a timely manner that the integrity of the seals has been compromised.

SUMMARY OF THE INVENTION

The foregoing and other objects are achieved by this invention, which provides, in accordance with a first apparatus aspect thereof, a conveyor roller having a drum shell, and a shaft extending outward of the drum shell. An end lid seal assembly is affixed to an axial end of the drum shell. The end lid seal assembly is provided with an end lid interposed between the drum shell and the shaft, a polymeric rotary seal, and a seal compression plate.

In one embodiment of this first apparatus aspect of the invention, there is additionally provided a fastener that extends through the seal compression plate and is fastened into the end lid. In a specific illustrative embodiment of the invention, the seal compression plate is fastened into the end lid by threaded engagement.

In a further embodiment, there is provided an embossed spring band for fastening the end lid against a mounting face. The embossed seal band ensures that the seal compression plate is pressed toward the end lid, and that a force is applied to the polymeric rotary seal.

In another embodiment there is provided a ring compression geometry on an axially inward face and about an inner circumference of the end lid. The ring compression geometry exerts a compressive force on the polymeric rotary seal when the end lid is urged toward the end lid.

In a still further embodiment, the seal compression plate is configured to have a ring compression geometry on its axially outward face about an inner circumference of the end lid. The ring compression geometry exerts a compressive force on the polymeric rotary seal when the seal compression plate is urged toward the end lid.

In accordance with a second apparatus aspect of the invention, there is provided a conveyor roller having a drum shell. An end lid assembly is provided with an end lid, an embossed spring band, and a mounting face that is affixed to the drum shell at an axial end of the drum shell. The end lid has a first cylindrical geometry with a first nominal diameter designed to mate with a second cylindrical geometry having a second nominal diameter on the mounting face, whereby when the embossed spring band is disposed radially between the mating first and second cylindrical geometries, the embossed

5

spring band is compressed to an extent that creates an interference fit between the two mating cylindrical geometries.

In one embodiment of this second apparatus aspect of the invention, there is additionally provided a polymeric seal that is disposed axially between the axially inward face of the end lid and the axially outward face of the drum shell about the outer circumference of the end lid. The end lid maintains a spring force about its outer circumference against the polymeric seal. In a specific illustrative embodiment of the invention, the end lid is configured to have a ring compression geometry on its axially inward face about the outer circumference of the end lid, for exerting a compressive force on the polymeric seal as the end lid is retained against the drum shell by the embossed spring band.

In another embodiment, the drum shell is configured to have a ring compression geometry on an axially outward face about the outer circumference of the end lid. Such a ring compression geometry exerts a compressive force on the polymeric seal as the end lid is retained against the drum shell by the embossed spring band.

In accordance with a third apparatus aspect of the invention, there is provided a conveyor roller that has a drum shell. There is additionally provided a cleaning system for rotary shaft seals. In accordance with the invention, the cleaning system has a shaft with first and second cleaning conduits, an inlet port attached to the first cleaning conduit, and an outlet port that is attached to the second cleaning conduit. An end lid is provided having an axially inward face. There are also provided a first axially outward polymeric rotary seal and a second axially outward polymeric rotary seal. A chamber is formed between the first and second axially outward polymeric rotary seals, into which the first and second cleaning conduits communicate. A seal compression plate and a seal spacer ring are also provided.

In one embodiment of this third apparatus aspect of the invention, there is provided a fastener. The chamber is formed between the first and second axially outward polymeric rotary seals, by the process of:

disposing an outward face of the first axially outward polymeric rotary seal axially inward of the inward face of the end lid;

disposing an outward face of the seal spacer ring axially inward of an inward face of the first axially outward polymeric rotary seal;

disposing an outward face of the second axially outward polymeric rotary seal axially inward of an inward face of the spacer ring;

disposing an outward face of the seal compression plate axially inward of the inward face of the second axially outward polymeric rotary seal; and

urging the seal compression plate toward the end lid by operation of the fastener.

In a further embodiment, the end lid is configured to have a ring compression geometry on an axially inward face about its inner circumference, for exerting a compressive force on the first axially outward polymeric rotary seal when the seal compression plate is urged toward the end lid.

In yet another embodiment, the seal spacer ring is configured to have a ring compression geometry on its axially outward face about the inner circumference of the end lid, which imposes an axial compressive force on the first axially outward polymeric rotary seals when the seal compression plate is urged against the end lid.

BRIEF DESCRIPTION OF THE DRAWING

Comprehension of the invention is facilitated by reading the following detailed description, in conjunction with the annexed drawing, in which:

6

FIG. 1 is a simplified schematic representation of a conventional motorized drum;

FIG. 2 is a simplified schematic representation of another conventional motorized drum;

FIG. 3(a) is a simplified end view of an embodiment of the motorized drum of the present invention with a partial cut away showing the key inserted in the central shaft for engaging the high torque coupler.

FIG. 3(b) is an axial cross-section of a motorized drum of a particular embodiment of the present invention, wherein an external rotor is connected to a cycloidal reducer utilizing a hollow bore input shaft within a drum shell, and wherein an extension shell component with integrated sprocket geometry is attached to the mounting face of the base unit;

FIG. 3(c) is a simplified section view across A-A of FIG. 3B, showing the mounting face;

FIG. 4 is an axial cross-section of a motorized drum of a particular illustrative embodiment demonstrating some of the aspects of the present invention, wherein an external rotor is connected to a cycloidal reducer utilizing a central input shaft within a drum shell;

FIG. 5 is an enlargement of the portion B-B of the simplified schematic cross-sectional representation of the embodiment of FIG. 4;

FIG. 6 is a simplified schematic cross-sectional representation of a portion of the stator of an outer rotor induction motor embodiment of the invention having twenty-four slots;

FIG. 7 is an enlargement of a fragmented portion of the simplified schematic cross-sectional representation of the stator embodiment of FIG. 6 showing two of the twenty-four slots in greater detail;

FIG. 8 is a simplified schematic cross-sectional representation of a rotor of the outer rotor induction motor embodiment of the present invention having thirty-two substantially round-shaped slots;

FIG. 9 is an enlargement of a portion of the simplified schematic cross-sectional representation of the rotor embodiment of FIG. 8 showing one of the thirty-two substantially round-shaped slots in greater detail;

FIG. 10 is a simplified schematic cross-sectional representation of rotor bars that are inserted through the substantially round-shaped slots of the rotor arrangement of FIGS. 7 and 8 and are fixed within an end-ring without requiring die-casting;

FIG. 11 is a simplified schematic representation of a winding distribution useful in the practice of the present invention;

FIG. 12 is a simplified magnetic flux diagram of an induction motor that illustrates the tight linkage between the stator and rotor under load conditions that is achieved by a specific illustrative embodiment of the invention;

FIG. 13(a) is a simplified schematic cross-sectional representation of a permanent magnet motor utilizing an outer turning rotor with magnets embedded within the rotor laminations;

FIG. 13(b) is a cross-sectional representation of the outer turning rotor lamination showing the bolt holes in the center of each magnet polarity pair;

FIG. 14(a) is a simplified magnetic flux diagram of an interior permanent magnet synchronous motor, utilizing an outer turning rotor. 14(b) is an enlarged view of the magnetic flux at the point where north south magnets are in close proximity;

FIG. 15 is a simplified schematic isometric representation of a permanent magnet rotor system having a permanent magnet rotor housing in which a plurality of permanent magnet elements are arranged in a spiral configuration;

FIG. 16 is a simplified schematic end plan representation of the permanent magnet rotor housing embodiment of FIG. 15;

FIG. 17 is a simplified schematic representation of section A-A of the permanent magnet rotor housing embodiment of FIG. 16;

FIG. 18 is a simplified schematic representation of an axial cross-section through an external rotor with a drum shell that is particularly suited for use in a motorized drum, and this is useful to describe the flow of cooling gas in a single centrifugal impeller embodiment of the invention;

FIG. 19 is a cross-section through a conventional cycloidal speed reducer, which is commonly mounted to a standard external motor;

FIG. 20 is a cross-section through a cycloidal speed reducer of the present invention, which is mounted within a motorized drum;

FIG. 21 is a simplified schematic representation of a motorized drum utilizing a harmonic speed reducer with a hollow bore input, wherein the major axis of the wave generator is in the horizontal position;

FIG. 22 is a simplified schematic representation of a motorized drum utilizing a harmonic speed reducer with a hollow bore input, wherein the major axis of the wave generator is in the vertical position;

FIG. 23 is a simplified isometric representation of the hollow bore input of the cycloidal reducer of the present invention, utilizing protruding tabs to receive motor input and utilizing integral eccentric raceways to engage input gears;

FIG. 24 is another simplified isometric representation of the hollow bore input of the cycloidal reducer of the present invention, utilizing protruding tabs to receive motor input and utilizing integral eccentric raceways to engage input gears;

FIG. 25 is a simplified partially exploded isometric schematic representation of the coupling between the outer rotor of an electric motor, a cycloidal speed reducer, and a central shaft of an embodiment of the invention.

FIG. 26(a) is a simplified schematic representation of a side plan view of a motorized drum constructed in accordance with the invention; FIG. 26(b) is a plan cross-sectional representation of a shaft coupler; and FIG. 26(c) is an end view of the motorized drum;

FIG. 27 is a simplified schematic partially cross-sectional side plan representation of the embodiment of FIGS. 26(a), 26(b), and 26(c) taken along section A-A of FIG. 26(a) and showing the coupling between the elements of the structure there within;

FIG. 28 is a simplified schematic representation of the coupling between the rotor of an electric motor, a cycloidal speed reducer, and a central shaft of an embodiment of the invention, wherein the high speed coupler has two slot pairs;

FIG. 29 is a simplified partially exploded isometric schematic representation of the coupling system between the rotor of an electric motor, a cycloidal speed reducer, and a central shaft of an embodiment of the invention, wherein the high speed coupler has two slot pairs;

FIG. 30 is a further simplified partially exploded isometric schematic representation of the coupling system between the rotor of an electric motor, a cycloidal speed reducer, and a central shaft of an embodiment of the invention, wherein the high speed coupler has two slot pairs;

FIG. 31 is an alternate simplified partially exploded isometric schematic representation of the coupling system between the rotor of an electric motor, a cycloidal speed reducer, and a central shaft of an embodiment of the invention, wherein the high speed coupler has two tab pairs instead of slots;

FIG. 32 is an alternate simplified partially exploded isometric schematic representation of the coupling system between the rotor of an electric motor, a cycloidal speed

reducer, and a central shaft of an embodiment of the invention, wherein the high speed coupler has one pair of tabs and one pair of slots;

FIG. 33 is an alternate simplified partially exploded isometric schematic representation of the coupling system between the rotor of an electric motor, a cycloidal speed reducer, and a central shaft of an embodiment of the invention, wherein the high speed coupler has a tab paired with a slot;

FIG. 34 is an alternate simplified partially exploded isometric schematic representation of the coupling system between the rotor of an electric motor and a cycloidal speed reducer of an embodiment of the invention, wherein the high speed coupler has slot pair in the horizontal axis with a tab/slot paired in the vertical axis;

FIG. 35 is an alternate simplified partially exploded isometric schematic representation of the coupling system between the rotor of an electric motor, a cycloidal speed reducer, and a central shaft of an embodiment of the invention, wherein a keyless bushing engages the central shaft rather than keys directly inserted into the central shaft;

FIG. 36 is an axial cross-section of a motorized drum of an embodiment of the present invention, wherein an extension shaft is mounted to the mounting face of the base unit;

FIG. 37 is an axial cross-section of a motorized drum of an embodiment of the present invention, wherein the clamp ring of the extension shaft is in direct contact with the mounting ring of the base unit, without the use of an intervening mounting face;

FIG. 38 is an axial cross-section of a motorized drum of a particular embodiment of the present invention, wherein an extension shell component is attached to the mounting face of the base unit and held in place by means of a large central nut;

FIG. 39 is an isometric exploded view of the mounting face system utilized in attaching extension shell components to the base unit of a motorized drum, as an embodiment of the present invention;

FIG. 40 is an isometric representation of an embossed spring band;

FIG. 41 is an isometric cut-away of one embodiment of the embossed spring band holding the end lid against the motorized drum of the present invention;

FIG. 42(a) is a simplified cross-sectional representation of an embodiment of the compression geometry utilized in the end lid where the end lid contacts the static drum shell seal in the motorized drum of the present invention and FIG. 42(b) is a simplified cross-sectional representation of an embodiment of the compression geometry utilized in the end lid where the end lid contacts the static drum shell seal in the motorized drum of the present invention in response to the application of an installation force, the end lid remaining in fixed relation by operation of an embossed band that is deformed upon installation;

FIG. 43 is an axial simplified cross-sectional representation of the end lid of the motorized drum of the present invention in one embodiment, wherein the end lid has a relatively thin wall in the radial distance between the embossed spring band 03420 and the outer periphery in order to maximize the spring-like characteristics of the end lid against the static drum seal;

FIG. 44 is a simplified cross-sectional representation of one embodiment of the compression geometry utilized in the end lid where the end lid contacts the rotary shaft seal of a motorized drum of the present invention;

FIG. 45 is a cut away of an exploded view of one embodiment of the rotary shaft seal compression system of a motorized drum of the present invention;

FIG. 46 is an isometric drawing of the end lid removal tool, as it is attached to the end lid of the motorized drum of the present invention;

FIG. 47 is an isometric exploded view of FIG. 46;

FIG. 48 is a simplified schematic representation of a specific illustrative embodiment of a fluid port that is useful in the sanitation of the motor using selectably evacuation or pressurization within the motor as well as a pair of fluid ports used to cycle cleaning fluids through an annular chamber in the seal region of the motorized drum of the present invention; and

FIG. 49 is a simplified schematic of a fluid port system useful in the sanitation of the motorized drum of the present invention, and more particularly in monitoring the state of the seals.

FIG. 50 is an axial cross-section of a motorized drum of a particular embodiment of the present invention, wherein an extension shell component is attached to the mounting face of the base unit using clamping bolts and the drum shell of the base unit has a chamfer that mates with a corresponding chamfer on the extension drum shell.

DETAILED DESCRIPTION

The following designations of items in the drawings are employed in the following detailed description:

Item #	Description
03000	Motorized drum
03010	Base unit
03100	Cycloidal Reducer
03110	Hollow bore eccentric input
03140	Cycloidal disk (external toothed gear)
03150	Primary guide pin support ring
03151	Secondary guide pin support ring
03153	Guide pin bushing
03160	Cycloidal reducer housing (internal toothed ring gear)
03161	Ring pin
03200	Motor (Permanent magnet)
03210	Central shaft
03220	Stator
03221	Stator laminations
03222	Stator windings
03223	Stator winding leads
03230	Rotor
03231	First rotor bearing
03232	Second rotor bearing
03233	Primary rotor end lid
03234	Secondary rotor end lid
03241	Rotor laminations
03242	Rotor lamination clamp bolt
03247	Rotor output tab
03310	High speed coupler
03350	High torque coupler
03351	High torque central shaft key
03410	Primary end lid
03420	Embossed spring band
03430	End lid mounting face
03440	Seal compression plate
03441	Fastener
03442	Rotary polymeric lip seal
03450	Static polymeric seal
03510	Mounting ring
03511	Primary spring ring
03512	Mounting face
03520	Extension clamp spacer
03530	Clamp ring
03531	Secondary spring ring
03532	Extension clamping bolt
03533	Mating cam face washers
03534	Bolt holder
03540	Seal compression plate
03541	Fastener

-continued

Item #	Description
03542	Rotary polymeric lip seal
03560	Extension shell attachment
03570	End lid attachment
03571	Embossed spring band
03572	Static seal
03700	Drum shell
03710	First base unit bearing
03711	Second base unit bearing
04000	Motorized drum
04111	Eccentric input shaft
04140	Cycloidal disk (external toothed gear)
04152	Guide pin
04153	Guide pin bushing
04160	Cycloidal reducer housing (internal toothed ring gear)
04161	Ring pin
04200	Motor (Induction)
04210	Stator shaft
04220	Stator
04221	Stator laminations
04230	Rotor
04231	First rotor bearing
04232	Second rotor bearing
07224	Stator slots
07225	Stator slots
07226	Stator winding retaining hook
08235	Rotor slot
1010	Inner turning rotor
1020	Helical gear reducer housing
10236	Rotor bar
1030	First partial shaft
1040	Motor housing
1050	Motor flange
1060	Second partial shaft
1070	Drum shell
11224	Stator wire portion
11225	Stator wire portion
11226	Stator wire portion
11227	Stator wire portion
13243	Embedded north rotor magnets
13244	Embedded south rotor magnets
13246	Rotor lamination bolt hole
15245	Rotor magnets - surface mounted
18233	Primary rotor end lid
18234	Secondary rotor end lid
18240	Rotor fins
18249	Air flow loop
19100	Cycloidal Reducer
19111	Eccentric input shaft
19140	Cycloidal disk (external toothed gear)
19141	Aperture
19152	Guide pin
19153	Guide pin bushing
19160	Cycloidal reducer housing (internal toothed ring gear)
19161	Ring pin
19162	Ring pin bushing
2010	Inner turning rotor motor
20100	Cycloidal Reducer
20110	Hollow bore eccentric input
20140	Cycloidal disk (external toothed gear)
20141	Aperture
20152	Guide pin
20153	Guide pin bushing
20160	Cycloidal reducer housing (internal toothed ring gear)
20161	Ring pin
20162	Ring pin bushing
2020	Cycloidal speed reducer
2030	First partial shaft
2040	Motor housing
2050	Support flange
2060	Second partial shaft
21000	Motorized drum
21800	Harmonic speed reducer
21810	Wave generator
21811	Elliptical ball bearing
21820	Flexible spline
21830	Rigid circular spline
21831	Affixing pin

50531	Spring ring
50532	Clamping bolt
50560	Extension shell attachment
50700	Drum shell

FIG. 1 is a simplified schematic representation of a prior art motorized drum that utilizes an inner turning rotor motor

12

1010, a helical gear reducer 1020 and a first partial shaft 1030 connected to the helical gear reducer housing 1020, which is connected to the motor housing 1040. Motor housing 1040 is connected to a motor housing flange 1050, which is connected to a second partial shaft 1060. This motorized drum is a closed, oil-filled, thermal system utilizing the oil (not shown) to transfer motor heat (not shown) to drum shell 1070.

FIG. 2 is a simplified schematic representation of a prior art motorized drum that utilizes an inner turning rotor motor 2010, a cycloidal reducer 2020 and a first partial shaft 2030 that is connected to the housing (not specifically designated) of cycloidal reducer 2020. The housing of cycloidal reducer 2020 is connected to a motor stator housing (not specifically designated) and a support flange 2050 that encompasses the motor. Support flange 2050 is further connected to a second partial shaft 2060.

This motorized drum is an open thermal system, utilizing external air (shown by curved arrows), which is urged into the motorized drum and flows across the motor and reducer and exits the opposite end of the motorized drum, to transfer the motor heat into the ambient environment.

FIG. 3(b) is a side plan axial cross-sectional representation of a motorized drum 03000 constructed as a specific illustrative embodiment of the invention of the present invention. In this embodiment, the radially interior periphery of external rotor 03230 rotates about the radially exterior stator 03220 and is connected to a cycloidal reducer 03100 utilizing a hollow bore input shaft 03110 within a drum shell 03700, and wherein an extension shell attachment 03560 is attached to the mounting face 03512 of base unit 03010.

The motorized drum 03000 of the present invention comprises a drum shell 03700 and the motor 03200 and cycloidal reducer 03100 are housed inside of drum shell 03700. Bearings 03710, 03711 are disposed at both end sections of the drum shell on the central shaft 03210 thereby constituting the base unit 03010. In this embodiment, an extension shell attachment 03560 is mounted to the mounting face 03512 on the right side of the base unit 03010. The base unit 03010 plus the mounted extension shell attachment 03560 are sealed forming a closed thermal system.

The motor output, which is a pair of tabs 03247 on the rotor 03230, is coupled to the cycloidal reducer input 03110, by means of a high speed coupler 03310 thus reducing the speed and increasing the torque. The cycloidal housing, which is an internal toothed ring gear 03160, is directly connected to drum shell 03700 so that the drum shell rotates about fixed central shaft 03210.

Stator 03220 of motor 03200 is affixed to central shaft 03210. The central shaft and stator winding leads 03223 pass through the center of the hollow bore eccentric input 03110 of the cycloidal reducer 03100 with sufficient clearance to accommodate the deflection that central shaft 03210 will experience in operation. Outer turning rotor 03230 is mounted to central shaft 03210 by means of rotor bearings 03231 and 03232.

The fixed reference point of the cycloidal reducer 03100 is affixed to central shaft 03210 by a high torque coupler 03350 and high torque central shaft key 03351 (FIG. 3a).

A primary end lid 03410 is attached to the base unit 03010 by means of an embossed spring band 03420 and an end lid mounting face 03430.

FIGS. 4 through 12 relate to an embodiment of the present invention, wherein the outer turning rotor is of an induction motor. FIG. 4 is a simplified axial cross-section through a motorized drum 04000 wherein a motor 04200 has an external rotor 04230 constructed in accordance with the principles of one embodiment of the invention. Outer turning rotor

13

04230 improves the torque density of the motor, whereby the same torque that is achievable in an inner turning rotor can be achieved in an outer turning rotor in either a smaller diameter or a shorter axial length. In FIG. 4, outer turning rotor **04230** is, as stated, of an induction motor. A stator **04220** is affixed to the stator shaft **04210** and external rotor **04230** is arranged to rotate about stator **04220** and stator shaft **04210**, which are fixed.

FIG. 5 is an enlargement of the portion B-B of the electric motor of FIG. 4. Here it is seen that the external rotor **04230** is rotatably supported on stator shaft **04210** by bearings **04231** and **04232** (only partially shown in FIG. 5), which in this specific illustrative embodiment of the invention are conventional ball bearings.

FIG. 6 is a simplified schematic transaxial cross-sectional representation of a portion of stator **04220** of outer rotor induction motor **04200** (not shown in this figure). The represented portion of stator **04220**, in some embodiments of the invention, corresponds to a ferromagnetic lamination element **04221** of stator **04220** (designated generally in this figure). In this specific illustrative embodiment of the invention, stator **04220** is configured to have twenty-four slots (each of which is individually numbered in the figure).

FIG. 7 is an enlargement of a fragmented portion of stator **04220** of FIG. 6. This figure shows two of the twenty-four slots in greater detail. As shown in this figure, representative slots **07224** and **07225** each extend substantially radially through stator **04220**, and have a substantially V-shaped configuration. Each such slot has, in this specific illustrative embodiment of the invention, substantially inward portions **07226** that reduce the circumferential dimension of the slot opening and thereby enhance the security with which the stator windings (not shown) are retained within the slots.

FIG. 8 is a simplified schematic cross-sectional representation of rotor **04230** of the outer rotor induction motor embodiment of the present invention having thirty-two substantially round-shaped slots **08235**.

FIG. 9 is an enlargement of a portion of the rotor embodiment of FIG. 8 showing one of the thirty-two substantially round-shaped slots in greater detail.

The rotor comprises 32 round shaped slots, as shown in FIGS. 8 and 9. The use of 32 bars ensures that there are no dangerous parasitic synchronous locking torques. The lowest common harmonic orders of the magneto-motive force between the stator with 24 magnetic teeth, as described above, and the rotor with 32 magnetic teeth, when there are two magnetic poles, is 95 and 97. This will create a minor torque dip at zero rotational speed. Hence, the outer rotor of the present application does not need to be skewed to eliminate the parasitic synchronous torques. Simple cross-sectional shapes, such as circular or square, for the bars will be adequate.

FIG. 10 shows conductive rotor bars **10236**, which in some embodiments of the invention are made of aluminum, and are, in this embodiment, inserted directly in the rotor slots **08235**, as herein illustrated. Short-circuit elements short circuit respective ends of the rotor conductors.

FIG. 11 is a simplified schematic representation of a winding distribution useful in the practice of the present invention. The 2-pole winding can be inserted automatically in a one layer distribution as shown in this figure. By way of example, in this specific illustrative embodiment of the invention winding a wire portion **11224** loops between slots numbered 1 and 14. Similarly, wire portion **11225** loops between slots numbered 23 and 12, wire portion **11226** loops between slots numbered 13 and 2, and wire portion **11227** loops between slots numbered 11 and 24.

14

FIG. 12 is a simplified flux diagram that illustrates the tight linkage between the stator and rotor under load conditions that is achieved by a specific illustrative embodiment of the invention. This figure illustrates the tight linkage between the stator and rotor under load conditions. It is seen from this figure that the highest flux-density occurs in the rotor back iron.

Since the rotor is located outside of the stator, the rotor diameter at the area facing the stator is larger than for an inner rotor configuration. The torque of a motor is proportional to the volume in the motor air-gap ($L \cdot \pi \cdot D^2 / 4$) where L is the active stack length and D is the rotor diameter. Because the diameter D is larger than that of an internal rotor induction motor, a reduced value for the stack length L is achievable for a given torque. An illustrative embodiment of the outer rotor induction motor of the present invention has a ratio D/L of 0.7. By comparison with the inner rotor induction motor configuration, the outer rotor solution has a higher (torque): (total volume) ratio.

The main loss component in a motor is the stator winding copper loss. The primary way of dissipating heat from the stator to the ambient environment in a conventional motorized drum having a closed thermal system is by means of conducting the motor heat to oil that in turn conducts the motor heat to the drum shell. The heat in the drum shell can then be conducted to the conveyor belt, if one exists, or convected to the ambient air, if no belt is present.

However, it is a significant feature of the present invention that oil is not used. Instead, a gas flow loop **18249** (see, FIG. 18), which in some embodiments is an air flow loop, is generated by use of a one or more axial air impellers having, for example, rotary fins. In the embodiment of FIG. 18, a centrifugal rotary fin **18240** is attached to the primary rotor end lid **18233**. This fan impeller fin, like the outer turning rotor, has a larger diameter than if it were attached to an inner turning rotor, and accordingly has greater effective gas flow. The gas flow loop has an axial toroidal flow path between the rotor and the stator and another toroidal axial flow path in the opposite direction between the rotor and the inner surface of the drum shell, which is substantially impermeable. The secondary rotor end lid **18234** is simply spoked to have minimal effect on the gas flow loop generated by centrifugal rotary fins **18240**.

In other embodiments that are not herein shown, axial fin designs are embedded into the primary and secondary rotor end lids to generate the gas flow.

An outer turning rotor significantly reduces the likelihood of catastrophic motor failure that would result from deflection and misalignment inherent in conventional motorized drums. In the present invention, as shown in FIG. 3, fixed stator shaft **03210** of motor **03200** serves as the fixed central shaft **03210** of motorized drum **03000** mounted to drum shell **03700** by means of base unit bearings **03710** and **03711**. In this construction, during operation, the only significantly deflecting part is fixed central shaft **03210**. Stator **03220** is directly affixed to central shaft **03210** and outer turning rotor **03230** is affixed to the fixed central shaft by rotor bearing **03231** in the primary rotor end lid **03233** and by rotor bearing **03232** in secondary rotor end lid **03234**. Therefore, stator **03220** and outer turning rotor **03230** move in tandem as the fixed central shaft **03210** deflects.

FIGS. 13-17 relate to an embodiment of the present invention wherein the outer turning rotor is of a permanent magnet motor. FIG. 13 is a cross-sectional representation of the outer turning permanent magnet motor **03200**. In this illustrative embodiment, magnets are embedded in magnet receiving slots between inner and outer circumferential peripheral sur-

15

faces of a ferromagnetic rotor element, such as a rotor **03230**, in polarity pairs of north magnets **13244** and south magnets **13243**. The rotor rotates around stator **03220**. The magnets are arranged so that every other magnet has an opposite polarity, thus forming an alternating pattern of north paired magnets **13244** and south paired magnets **13243**. The magnets shown are rectangular with a magnet face intermediate of two corners. Further, the magnet pairs are arranged so that the adjacent polarity corners are radially outward of the distal same-polarity corners. In this fashion, the magnetic flux is focused by the angled pairs of magnets and therefore causes a feedback in the stator **03220** that is sensed by the controlling power electronics (not shown) to determine the position of rotor **03230** relative to stator **03220**. One advantage of this design is that no additional physical encoders or sensors are required to be inserted into motorized drum **03000** for the controlling power electronics to drive motor **03200** properly.

Further, in this illustrative embodiment, rotor **03230** does not utilize a housing. Instead, rotor lamination **03241**, shown in FIG. **13b**, utilizes a circumferential gap or hole **13246** between the same polarity magnet pairs through which the lamination stack is fastened between both rotor end lids by means of rotor lamination clamp bolt **03242** (FIG. **3**). This design minimizes the overall diameter of motor **03200**, enabling achievement of greater torque density.

FIGS. **14a** and **14b** further illustrate the magnetic flux circuit through the rotor laminations pattern that is created with this illustrative embodiment.

FIGS. **15**, **16**, and **17** illustrate another embodiment of the permanent magnet motor. In this embodiment, the magnets are not embedded into the outer turning rotor, but rather the magnets **15245** are surface mounted to the interior periphery (not specifically designated) of the rotor housing. In this embodiment, the magnets are configured in a spiral, which reduces cogging torque. However, in other embodiments, the spiral, or helical, configuration is not required and the magnets are surface mounted axially along the inner periphery of the rotor housing, with an adhesive, for example.

FIG. **19** is a cross-section representation through a conventional cycloidal speed reducer **19100**, which is commonly mounted to a standard external motor by bolting the face (not specifically designated) of the cycloidal reducer housing to the external motor (not shown in this figure). In this representation of prior art, cycloidal reducer housing **19160** functions as the fixed reference point of the reducer. Around the inner periphery of the cycloidal reducer housing **19160**, ring pins **19161** are inset. In some low reduction ratios, the ring pins **19161** are encased by ring pin bushings **19162**, which, in turn, function as the internal-toothed ring gear that engages the external toothed gear or cycloidal disk **19140**. In other higher reduction ratios, not shown, the ring pins are inset in the housing without bushings and engage the cycloidal disk directly.

Eccentric input shaft **19111** rotates and urges the cycloidal disk **19140** to oscillate about the ring pin bushings **19162** of the internal-toothed ring gear. In FIG. **19**, there are twelve ring pin bushings **19162**, or internal gear teeth, about the inner circumference of the cycloidal reducer housing **19160** and there are eleven lobes, or external gear teeth, about the outer circumference of the cycloidal disk **19140**. Each full revolution of the eccentric input shaft **19111** causes the lobes of the cycloidal disk **19140** to engage each subsequent ring pin bushing **19162**. Therefore, in this illustrative embodiment, because the cycloidal disk **19140** has eleven lobes and there are twelve ring pin bushings **19162**, the cycloidal disk **19140** has engaged only eleven of the twelve ring pin bushings **19162**, effectively causing the cycloidal disk **19140** to rotate

16

backward one ring pin bushing. Generally, a cycloidal disk has n external teeth engaging at least $n+1$ internal teeth in the ring gear. As the cycloidal disk **19140** rotates, apertures **19141** in the cycloidal disk **19140** engage guide pins **19152** and guide pin bushings **19153**, causing the guide pins **19152** and bushings **19153** to rotate with the cycloidal disk **19140**. These guide pins **19152** and bushings **19153** are affixed to a guide pin support ring (not shown), which functions as the output of the reducer.

This concept is clearly employed in the conventional drum motor of FIG. **2**, where the face of cycloidal reducer housing **19160** (labeled **2020** in FIG. **2**) is bolted to a conventional motor. An output shaft **2030** of FIG. **2** is rigidly connected internally to the guide pins **19152** and guide pin bushings **19153** of FIG. **19**.

FIG. **20** is a cross-section through a cycloidal speed reducer of the present invention **20100**, which is mounted within a motorized drum (not shown in this figure). Unlike the prior art where the face of the cycloidal reducer housing is bolted to the motor, in this illustrative embodiment, cycloidal reducer housing **20160**, which is the internal ring gear, is mounted directly to the inner periphery of the drum shell **03700**. Therefore, cycloidal reducer housing **20160** does not serve as the fixed reference point of the reducer, but instead serves as the output of the reducer, rotating synchronously with the drum shell **03700**.

In the embodiment of FIG. **20**, there are shown twenty ring pins **20161** and twenty ring pin bushings **20162** about the inner circumference of the cycloidal housing **20160**, which function as the inner ring gear. There are nineteen lobes about the outer circumference of the cycloidal disk **20140**. In this embodiment, the guide pins **20152** and guide pin bushings **20153** are affixed to a guide pin support ring **03150**, also referred to as a guide pin housing, (not shown in FIG. **20**) that is coupled to the central fixed shaft **03210** (not shown in FIG. **20**) by means of a high torque coupler **03350** (not shown in FIG. **20**) in order to function as the fixed reference point of the cycloidal reducer **20100**. As the eccentric input shaft **20110** rotates, the apertures **20141** in the cycloidal disk **20140** engage guide pins **20152** and guide pin bushings **20153**, the cycloidal disk oscillates around the guide pins **20152** and guide pin bushings **20153**. This oscillation movement of cycloidal disk **20140** engages each subsequent ring pin bushing **20162**. Since there are more ring pin bushings **20162** than lobes on the cycloidal disk **20140**, the internal ring gear of the cycloidal housing **20160** is advanced one ring pin bushing **20153** for every full rotation of the eccentric input shaft **20110**. Thus the internal ring gear rotates at a reduced rate relative to the input shaft.

In the preferred illustrative embodiment of FIG. **20**, eccentric input shaft **20110** of the cycloidal reducer **20100** is tubular with a hollow bore, thereby enabling the stator winding leads **03223** (not shown in FIG. **20**) and the central shaft **03210** (not shown in FIG. **20**) of the motorized drum **03000** (not shown in FIG. **20**) to pass through the center of the cycloidal reducer **20100**. FIG. **3** of the same preferred embodiment shows the stator winding leads **03223** and the central shaft **03210** passing through the hollow bore eccentric input shaft **03110** of the cycloidal reducer **03100**. An advantage of this design is that the cycloidal reducer **03100** is mounted to the drum shell **03700**, which is the most rigid element of the motorized drum **03000**. There is sufficient clearance between the hollow bore input shaft **20110** and the central shaft **03210** so that when the central shaft deflects, it has no impact upon the cycloidal reducer **03100** because it has no contact with the hollow bore eccentric input shaft **20110**.

17

A further advantage of the preferred embodiment of FIGS. 3 and 20 is that the heat generated from the rolling action of the cycloidal reducer elements is conducted immediately to the drum shell 03700 by means of the direct contact of the cycloidal reducer housing 20160, 03160 to the drum shell 03700.

By engaging the cycloidal housing 20160 directly to the drum shell 03700, a larger cycloidal reducer 20100 can be used within a given drum shell diameter, thus enabling a greater torque density of the motorized drum 03000 for a given axial length. As cycloidal reducers are inherently axially compact, the torque density is maximized for both the axial length and available internal diameter of the drum shell.

In some embodiments where high speed reductions are required, another embodiment of a high torque reducer is harmonic speed reducer 21800 shown in FIG. 21. FIG. 21 is a simplified schematic representation of a motorized drum 21000 that utilizes a harmonic speed reducer 21800 with a hollow bore input, wherein the major axis of wave generator 21810 is in the horizontal position. Harmonic speed reducer 21800 operates using the same basic principles as a cycloidal reducer, in that the rigid circular spline 21830 has more teeth than the flexible spline member 21820 being driven by the wave generator 21810. Every revolution of the wave generator 21810 effectively causes the rigid circular spline 21830 to advance by the amount of teeth that exceed the number of teeth of the flexible spline member 21820.

In this embodiment, rigid circular spline 21830 is mounted directly to drum shell 03700 and functions as the output of harmonic speed reducer 21800. Flexible spline 21820 is affixed to the central shaft by means of an affixing pin 21831 and functions as the fixed reference point of the harmonic speed reducer 21800. Wave generator 21810, which is the input of harmonic speed reducer 21800, is hollow so as to allow stator lead wires 03223 and central shaft 03210 to pass through the center of harmonic speed reducer 21800.

FIG. 22 shows the same harmonic speed reducer of FIG. 21, wherein the major axis of the wave generator is in the vertical position.

FIGS. 23 and 24 are simplified isometric representations of the hollow bore input 03110 of the cycloidal reducer of the present invention. It is of a substantially tubular configuration utilizing protuberances referred to as protruding tabs 23130 to receive the motor input and utilizing integral eccentric raceways 23120 to engage the cycloidal disk input gears (not shown). In this illustrative embodiment, the input shaft of the cycloidal reducer is hollow, enabling the central shaft and stator winding leads to pass through the center of the cycloidal reducer.

FIG. 25 is a simplified partially exploded isometric schematic representation that is useful to illustrate the power transmission coupling arrangement between the outer rotor of an electric motor, a cycloidal speed reducer, and a central shaft of an embodiment of the invention. This figure demonstrates how the present invention accommodates the misalignment and deflection inherent in all motorized drums in an axially compact manner.

Central shaft 03210 of the motor 03200 extends throughout motorized drum 03000 (not specifically designated in this figure), specifically extending through the center of the hollow bore eccentric input shaft 20110 of the cycloidal reducer. In this preferred illustrative embodiment, the angular and concentric misalignments between motor 03200 and eccentric input shaft 20110 of cycloidal reducer caused by the deflection of central shaft 03210, are accommodated by a high speed coupler 03310.

18

The protruding rotor tabs 03247 engage the slots on the outer circumference of the axially narrow high speed coupler 03310. Additionally, protruding tabs 23130 of hollow bore eccentric input shaft 20110 of the cycloidal reducer engage slots in the inner circumference of high speed coupler 03310. Proper clearance between the outer slots of the high speed coupler 03310 and rotor tabs 03247, and proper clearance between the inner slots of high speed coupler 03310 and hollow bore eccentric input shaft tabs 23130, as well as proper clearance between the outer diameter of central shaft 03210 and the inner diameter of high speed coupler 03310, enable the coupler to angle and slide across the various driving faces.

Guide pins 20152 and guide pin bushings 20153 around which cycloidal disks 20140 oscillate are affixed to primary guide pin support ring 03150. Primary guide pin support ring 03150 has internal slots on the axial side of the primary guide support ring opposite motor 03200. These internal slots receive the protruding tabs of high torque coupler 03350. High torque coupler 03350 has keyways on the inner circumference and is affixed to the central shaft by shaft keys 03351. In this way, the fixed reference point of the cycloidal reducer is effectively connected to central shaft 03210.

FIG. 26a is a simplified schematic representation of motorized drum 03000, having a coupler arrangement (not shown in this figure) constructed in accordance with the invention. FIG. 26b is a plan cross-sectional representation of a shaft coupler 03350, and FIG. 26c is an end view of motorized drum 03000. These figures show motorized drum 03000 to have a drum shell 03700 arranged to be rotatable about the central motor shaft 03210. The drum shell is sealed on the left-hand side of FIG. 26a to central motor shaft 03210 by an end lid 03410.

FIG. 27 is a simplified cross-sectional representation of the embodiment of FIG. 25 taken along section A-A of FIG. 25a and showing the coupling between the motor, the reducer and the shaft. As shown in this figure, an electric motor 03200 is coupled by means of high speed coupler 03310 noted above that is coupled to the cycloidal reducer input 27110. In this specific illustrative embodiment of the invention, the cycloidal reducer fixed reference 27150 is connected to central motor shaft 03210 by high torque coupler 03350. Drum shell 03700 is urged into rotation by virtue of its connection to the cyclo drive output 27160. High torque coupler 03350 prevents rotatory motion of cycloidal reducer fixed reference 27150 relative to central motor shaft 03210, while simultaneously accommodating for misalignment of central shaft 03210 relative to the cycloidal reducer fixed reference 27150 when the central shaft 03210 is flexed under load. High speed coupler 03310 also accommodates for misalignment between motor 03200 and the cycloidal input 27110 that results from the flexing of central motor shaft 03210. In this cross-sectional representation, rotor tabs 03247 are not seen because one is outside the surface of the figure and the other is behind the central motor shaft.

FIG. 28 is a simplified schematic representation of the coupling between rotor 03230 of electric motor 03200, cycloidal reducer 03100, and central shaft 03210 of an embodiment of the invention.

FIG. 29 is a simplified partially exploded isometric representation of the coupling system between rotor 03230 of electric motor 03200, cycloidal reducer 03100, and central motor shaft 03210.

FIG. 30 is another simplified partially exploded isometric representation, viewed from a second angle, of the coupling system between rotor 03230 of electric motor 03200, cycloidal reducer 03100, and central motor shaft 03210. Elements of structure that have previously been discussed are similarly

19

designated. As shown in these figures, the high speed coupler is configured to have two radially outward slots about the outer circumference to receive rotor tabs **03247** of motor **03230**, and two radially inward slots about the inner circumference to receive the protruding tabs of cycloidal reducer input **27110**. The slots or notches of the high speed coupler function as key ways and are arranged in substantially 90° displacement relative to each other.

The high speed coupler has four active orthogonal driving faces at any point in time. In FIG. 35, which shows an illustrative embodiment, two of the active driving faces **35312**, **35314** are parallel to each other and can be considered the first pair of the orthogonal driving faces; and the other two active driving faces **35316**, **35318** are parallel to each other and can be considered the second pair of orthogonal driving faces. In this illustrative arrangement, the first pair of active drive faces is orthogonal to the second pair of active drive faces.

Two orthogonal driving faces **35312**, **35314** actively receive torque from two respective orthogonal driving faces **35311**, **35313** from the rotor tabs, which can be considered drive elements.

Two orthogonal driving faces **35318**, **35316** transmit torque to two respective orthogonal driving faces **35317**, **35315** of cycloidal reducer input **27110**, which can be considered to have a pair of driven elements. Therefore, a total of eight orthogonal driving faces are constantly engaged during operation.

A variety of orthogonal arrangements are possible. FIG. 31 is a simplified schematic isometric representation that shows a high speed coupler **31310** with protruding tabs about the outer circumference to receive slots from the outer turning rotor, and protruding tabs about the inner circumference to receive slots in the hollow bore eccentric cycloidal reducer input shaft.

FIG. 32 is a simplified schematic isometric representation that shows slots about the inner circumference of high speed coupler **32310** to receive the rotor tabs, and protruding tabs about the inner circumference of high speed coupler **32310** to receive the slots of the hollow bore eccentric input shaft of the cycloidal reducer.

FIG. 33 is a simplified schematic isometric representation that further shows two slots about the inner circumference of high speed coupler, also referred to as an engagement coupler or speed coupler, **33319** to receive the rotor tabs, and one protruding tab about the inner circumference and one slot about the inner circumference in order to receive a corresponding slot and tab from the hollow bore eccentric input shaft of the cycloidal reducer.

FIG. 34 is a simplified schematic isometric representation that shows high speed coupler **34310** of this illustrative embodiment more clearly by eliminating the central shaft from the drawing. An advantage of this high speed coupling is that angular and concentric misalignment between the rotor and the input of the cycloidal reducer is accommodated, yet uninterrupted torque is delivered to the cycloidal reducer.

As noted, the cycloidal fixed reference **27150** of FIGS. 29-30 is fixed relative to central shaft **03210**, but is permitted to accommodate misalignment resulting from the flexing of the central shaft when the system is under lateral load. This accommodation is achieved by a reference coupler arrangement in which a high torque coupler, also referred to as an engagement coupler or reference coupler, **03350** is rotationally fixed to central shaft **03210** by engagement with a radial shaft key **03351** that engages a corresponding keyway that extends longitudinally within high torque coupler **03350**. High torque coupler **03350** is circumferentially configured with protruding tabs to fit within a corresponding slot in the

20

fixed reference of the cycloidal reducer. Therefore, the same concept of orthogonal driving faces employed with the high speed coupler of FIG. 35 is employed, as well, by the high torque coupler.

FIG. 35 is another simplified schematic representation of an illustrative embodiment of the means by which the high torque coupler is affixed to the shaft. Rather than using keyways with matching keys, a keyless bushing **35352** is used. The advantage of a keyless bushing is that a smaller diameter central shaft can be used in the practice of the invention.

FIG. 36 is a simplified axial cross-sectional representation of a motorized drum **36000** of an embodiment of the present invention, wherein an extension shaft **36560** is mounted to mounting face **36512** of base unit **03010** (denoted in FIG. 3). Extension shaft **36560** is rigidly connected to clamp ring **36530** that is affixed against mounting face **03512** by use of a plurality of fasteners (extension clamping bolts **36532**) extending through clamp ring **36530** and threading into mounting ring **03510** on the opposite side of mounting face **03512**. The mounting ring is located some distance from the determined region of rotary power delivery or where the reducer delivers power to the drum shell.

Axially inward of mounting face **03512** is mounting ring **03510**. The mounting ring **03510** has a chamfer on the outer circumference of its axially outward face. The chamfer of mounting ring **03510** is in direct contact with spring ring **03511**. The spring ring, which may be formed of a hardened metal with an aggressive texture, may have a cross-sectional geometry that is generally circular or diamond or rectangular, for example. Spring ring **03511**, mounting ring **03510**, and mounting face **03512** are held in place by means of mounting ring alignment bolts **36513** when an attachable component is not mounted to mounting face **03512**. In this illustrative embodiment, extension clamping bolts **36532** are used to draw clamp ring **36530** toward mounting ring **03510** thus causing the chamfer on mounting ring **03510** to be drawn against spring ring **03511**, forcing the spring ring to expand radially into drum shell **03700**, thereby transmitting the transaxial forces of extension shaft **36560** into drum shell **03700**.

FIG. 37 is a simplified axial cross-sectional representation of a motorized drum **37000** of a further embodiment of the present invention, wherein clamp ring **37530** of extension shaft **37560** directly contacts with mounting ring **37510** of base unit **03010** (denoted in FIG. 3), without the use of an intervening mounting face. In this embodiment, mounting ring **37510** has a similar chamfer as in FIG. 36 and is drawn similarly against spring ring **37511** by use of fasteners extending through clamp ring **37530**.

FIG. 38 is a simplified axial cross-sectional representation of a motorized drum of a particular embodiment of the present invention, wherein an extension shell attachment **03560** (denoted in FIG. 3) is attached to mounting face **03510** of base unit **03010** (denoted in FIG. 3) and held in place by means of a large central nut **38551**. Before mounting extension shell attachment **03560**, threaded flange **38550** is mounted to mounting face **03512** by use of a plurality of fasteners (not shown) that thread into mounting ring **03510**, thereby drawing the chamfer of mounting ring **03510** against spring ring **03511** such that spring ring **03511** expands radially into drum shell **03700**. Additionally, clamp ring **03530** is inserted into extension shell attachment **03560** and a secondary spring ring **03531** is inserted into a circumferential groove in the inner periphery of extension shell attachment **03560** axially outward of clamp ring **03530**. Then, extension shell attachment **03560** is placed against base unit **03010** and a central nut **38551** is inserted from opposite end of shell extension attachment **03560**. This central nut **38551** is treaded onto threaded

21

flange **38550**, thereby drawing clamp ring **03531** against secondary spring ring **03531** causing secondary spring ring **03531** to expand radially into extension shell attachment **03560**.

FIG. **39** is an isometric exploded view of the mounting face system utilized in attaching extension shell component **03560** to base unit **03010** of a motorized drum **03000**, as an embodiment of the present invention. In this embodiment, rather than using one central nut, a plurality of extension clamping bolts **03532** are used with mating cam faced washers **03533**. The same principles demonstrated in FIG. **38** are shown in FIG. **39**. Additionally, a bolt holder **03534** aids in mounting of extension shell attachment **03560** by assuring the extension clamping bolts **03532** remain in clamp ring **03530** during installation, while accommodating for the extra distance required by extension clamping bolts **03532** that are not yet threaded into mounting ring **03510**.

The end lid is connected to the motorized drum by means of an embossed spring band. FIG. **40** is a simplified representation of an embossed spring band **03420**, also known as a tolerance ring.

FIG. **41** is an isometric cut-away of one embodiment of embossed spring band **03571** that holds end lid **03570** against the motorized drum in a drum shell closure arrangement of the present invention. The embossed spring band **03571** is disposed between two concentric protuberances, also referred to as cylindrical geometries, of end lid **03570** and mounting face **03512** and when the two concentric protuberances are nested together in an end lid assembly, embossed spring band **03571** is compressed creating an interference fit between the two concentric protuberances. The mating concentric protuberances of the end lid and the mounting face have different nominal diameters.

In another illustrative embodiment, a static polymeric seal is disposed between the end lid and the drum shell. FIG. **42(a)** is a simplified cross-sectional representation of such an embodiment. A polymeric seal **03572** is enclosed between end lid **03570** and drum shell **03700**. A ring compression geometry is about the outer circumference of the axial inward face of end lid **03570**. When end lid **03570** is held in place by the embossed spring ring, the ring compression geometry imposes a compressive force on seal **03572**.

In another embodiment, not shown in figure, the ring compression geometry is on an axially outward face of the drum shell about an outer circumference of the end lid.

FIG. **42(b)** is a simplified cross-sectional representation of an embodiment of the compression geometry utilized in the end lid where the end lid contacts the static drum shell seal in the motorized drum of the present invention and the ring compression geometry utilized in the end lid where the end lid contacts the rotary seal, also referred to as radial seal, in response to the application of an installation force, the end lid remaining in fixed relation to the polymeric rotary seal by operation of an embossed spring band that is deformed upon installation. Examples of rotary seals include rotary lip seals, rotary shaft seals or polymeric rotary lip seals. The embodiment of FIG. **42(b)** bears similarity to that of FIG. **42(a)**, and accordingly, elements of structure that have previously been discussed are similarly designated.

FIG. **43** is a simplified cross-sectional representation of another illustrative embodiment wherein a compressive force is maintained against seal **03450** by designing end lid **03410** with a thin wall, also referred to as an annular web, in the radial distance between the embossed spring band and the outer diameter to create a spring-like effect resulting from the axially resilient characteristic of the annular web. In this embodiment, the central portion of the end lid is held axially

22

inward by embossed spring band **03420** slightly farther than the natural contact point between the outer portion of end lid **03410** and outer static seal **03450** thereby maintaining a constant compressive force against static seal **03450**.

Inasmuch as end lid **03570** covers mounting face **03512** on one side of motorized drum **03000**, and inasmuch as compressed embossed spring band **03571** requires three tons of force to remove it, end lid **03570** has been designed with a geometry that mates with a removal tool clamp for simple removal in the field. FIG. **46** is a simplified isometric representation of one embodiment of the end lid removal tool as it is attached to the end lid of the motorized drum. FIG. **47** is a simplified isometric exploded representation of the embodiment of FIG. **46**. End lid **03410** has a recessed, outer circumferential geometry **46920**, also referred to as an end lid recess. Removal tool clamp **46940** has a recessed, inner circumferential geometry **46930**, also referred to as a tool recess, that corresponds to geometry **46920** of end lid **03410**. When removal tool clamp **46940** is placed over end lid **03410**, two recessed geometries **46920**, **46930** form a circular channel. A joining cord **46910** of a slightly smaller diameter than the circular channel is inserted through a tangential hole, or inlet, in removal tool clamp **46940**. The inserted joining cord **46910** effectively locks end lid **03410** to removal tool clamp **46940**, which can now be easily removed with a force generating arrangement, such as slide hammer **46950**.

FIG. **44** is a simplified cross-sectional representation of one embodiment of the compression geometry utilized in the end lid where the end lid contacts the rotary shaft seal of the motorized drum. A polymeric seal **03542** is placed directly against end lid **03570**. End lid **03570** has a ring compression geometry on its axial inward face about its outer circumference. A seal compression plate **03540** is attached to the end lid by a plurality of fasteners **03541**, compressing seal **03542** between seal compression plate **03540** and end lid **03570** to form an end lid seal assembly. A significant compressive force is applied at the ring compression geometry of end lid **03570** preventing ingress of bacteria between seal **03542** and end lid **03570**.

In another embodiment, not shown in figure, the ring compression geometry is on a axially outward face of the seal compression plate about an inner circumference of the end lid.

FIG. **45** is a simplified partially cross-sectional representation of an embodiment of the rotary shaft seal compression system of a motorized drum.

FIG. **48** is a simplified schematic representation of a cleaning-in-place system for the rotary shaft seals of the motorized drum. The cleaning-in-place system includes:

- a shaft **48210** with first cleaning conduit **48610** and second cleaning conduit **48611**;
- an inlet port **48620** attached to first cleaning conduit **48610**;
- an outlet port **48621** attached to second cleaning conduit **48611**;
- an end lid **48570**;
- a first axially outward polymeric radial seal **48630**;
- a second axially outward polymeric radial seal **48631**;
- an annular chamber **48613** formed between first and second radial seals **48630**, **48631**;
- a seal compression plate **48540**;
- a seal spacer ring **48541**; and
- a plurality of fasteners.

In this illustrative embodiment, seals **48630**, **48631** are stacked between end lid **48570** and seal compression plate **48540** and separated by seal spacer ring **48541**, thus forming annular chamber **48613**. A plurality of fasteners draw seal

23

compression plate **48540** axially toward end lid **48570**. In a preferred embodiment, end lid **48570** includes a ring compression geometry on its axial inward face about its inner circumference (not shown in FIG. **48**), which imposes a compressive force against radial seal **48630**. In another embodiment (also not shown in FIG. **48**) a ring compression geometry is on an axial outward face of the seal spacer ring about an inner circumference of the end lid.

Cleaning agents are delivered through inlet port **48620** into first cleaning conduit **48610** and into annular chamber **48613** and exit second cleaning conduit **48611** and outlet port **48621**. When desired, outlet port **48621** can be used to restrict the flow, thus building greater pressure in annular chamber **48613**. When this pressure increases sufficiently, polymeric seal **48630** will be deflected outward and up and the cleaning fluid will pass between the radial face of seal **48630** and the surface of shaft **48210**.

FIG. **48** further has a fluid conduit **48612** and a fluid port **48622** wherein fluid can be inserted or removed from drum chamber **48615**, which is a sealed region.

FIG. **49** is a schematic of a seal monitoring system incorporating a conveyor component known as a drum motor. The seal monitoring system is comprised, in this embodiment, of a sealed drum chamber **48615**, from which proceeds a fluid line **49100** in which, there is a sensor **49200** to measure pressure that reports to controller **49300**. Subsequent to said sensor **49200** is a valve **49400** subsequently connected to pump **49500**. Both the valve **49400** and pump **49500** may be controlled by the controller **49300**. Pump **49500** may be capable of adding or subtracting fluids, particularly gases, to or from the drum chamber **48615**. Alternatively, the sensor **49200** could be incorporated in a manner other than shown to measure flow of the fluid in said fluid line **49100**. Additionally, the sensor **49200** could be mounted internal to the sealed drum chamber **48615** and may be attached to fluid line **49100** or it may be connected to the external environment in some other manner.

FIG. **50** is an axial cross-section of a motorized drum of another particular embodiment of the present invention, wherein an extension shell attachment **50560** is attached to the mounting ring **50510**. In this embodiment, the drum shell **50700** is fitted with an internally beveled chamfer and the extension shell attachment **50560** is fitted with a mating externally beveled chamfer, referred to collectively as mating chamfers **50450**, by which the drum shell **50700** and the extension shell attachment **50560** are drawn together by a plurality of extension clamping bolts **50532** threading into the mounting ring **50510**.

Axially inward of the mounting face **50512** is the mounting ring **50510**. The mounting ring **50510** has a groove on the periphery of the outer circumference of its axially outward face. This groove is in direct contact with the spring ring **50511**.

Axially inward of the chamfered end of the extension shell attachment **50560** is a radially installed groove in which a spring ring **50531** is fitted. Axially inward of the spring ring **50531** is the clamp ring **50530**. The extension clamping bolts **50532** are used to draw the clamp ring **50530** toward the mounting ring **50510** thus causing the chamfer on the extension shell attachment **50560** to mate coaxially under compression with the chamfer on the drum shell **50700**, resulting in mating chamfers **50450**, thereby transmitting the transaxial forces of the extension shell attachment **50560** into the drum shell **50700**.

In summary, the foregoing is directed in part to:
eliminating the need for oil in the motor system, which poses a risk of cross contamination in sanitary applications;

24

increasing the torque density of the motor within a fixed diameter and motor length;

providing greater stability with variable loads;

transmitting core stator heat to the drum shell through via a gas with the use of circumferential gas turbulence between the stator and the rotor and between the rotor and the drum shell where it can be removed by the belt;

avoiding the need for additional position sensors to communicate the rotor position to the power electronics with the use of magnets, in some embodiments, that are embedded in the lamination stack and thereby cause a variation in magnetic flux around the circumference of the rotor, which variation can be detected by the power electronics that are connected to the stator windings; and

accommodating the deflection caused through belt pull.

Although the invention has been described in terms of specific embodiments and applications, persons skilled in the art can, in light of this teaching, generate additional embodiments without exceeding the scope, or departing from the spirit, of the invention described herein. Accordingly, it is to be understood that the drawing and description in this disclosure are proffered to facilitate comprehension of the invention, and should not be construed to limit the scope thereof.

What is claimed is:

1. A conveyor roller comprising:

a drum shell;
a shaft extending outward of the drum shell; and
an end lid seal assembly affixed to an axial end of said drum shell, said end lid seal assembly having:
an end lid interposed between said drum shell and said shaft;
a polymeric rotary lip seal; and
a seal compression plate axially inward of said polymeric rotary lip seal,
wherein said polymeric rotary lip seal is axially compressed between said seal compression plate and said end lid.

2. The conveyor roller of claim 1, wherein there is further provided a fastener extending through said seal compression plate and fastened into said end lid.

3. The conveyor roller of claim 1, wherein there is further provided an embossed spring band for fastening said end lid against a mounting face, whereby said seal compression plate is pressed toward said end lid and applies a force to said polymeric rotary lip seal.

4. The conveyor roller of claim 1, wherein there is further provided a ring compression geometry on an axially inward face and about an inner circumference of said end lid, for exerting a compressive force on said polymeric rotary lip seal when said seal compression plate is urged toward said end lid.

5. The conveyor roller of claim 1, wherein said seal compression plate is configured to have a ring compression geometry on its axially outward face about an inner circumference of said end lid, for exerting a compressive force on said polymeric rotary lip seal when said seal compression plate is urged toward said end lid.

6. A conveyor roller comprising:

a drum shell;
an end lid assembly having:
an end lid;
an embossed spring band; and
a mounting face affixed to said drum shell at an axial end of said drum shell, said end lid having a first cylindrical geometry with a first nominal diameter designed to mate concentrically with a second cylindrical geometry having a different second nominal diameter on said mounting face, whereby when said embossed

25

spring band is disposed radially between the mating first and second cylindrical geometries, said embossed spring band is compressed to an extent that creates an interference fit between the two concentrically mating cylindrical geometries.

5

7. The conveyor roller of claim 6, wherein there is additionally provided a polymeric seal disposed axially between an axially inward face of said end lid and an axially outward face of said drum shell about the outer circumference of said end lid.

10

8. The conveyor roller of claim 7, wherein said end lid maintains a spring force about its outer circumference against said polymeric seal.

9. The conveyor roller of claim 8, wherein said end lid is configured to have a ring compression geometry on its axially inward face about the outer circumference of the end lid, for exerting a compressive force on said polymeric seal as said end lid is retained against the drum shell by said embossed spring band.

15

10. The conveyor roller of claim 7, wherein said drum shell is configured to have a ring compression geometry on an axially outward face about the outer circumference of said end lid, for exerting a compressive force on said polymeric seal as said end lid is retained against said drum shell by said embossed spring band.
